

17) Write a python program for set of blocks encoded with the RSA algorithm and we don't have the private

key. Assume $n = pq$, e is the public key. Suppose also someone tells us they know one of the plaintext blocks has a common factor with n . Does this help us in any way?

PROGRAM:-

```
import math
```

```
def gcd(a, b):
```

```
    while b:
```

```
        a, b = b, a % b
```

```
    return a
```

```
def gcd_attack(n, plaintext_block):
```

```
    """
```

```
    Attempts to factor n using a plaintext block with a common factor with n.
```

```
    """
```

```
    factor = gcd(n, plaintext_block)
```

```
    if 1 < factor < n:
```

```
        p = factor
```

```
        q = n // p
```

```
        return p, q
```

```
    else:
```

```
        return None, None
```

```
# Example inputs
```

```
n = 3599 # suppose this is the public RSA modulus
```

```
e = 31 # public exponent
```

```
# Attacker knows that one plaintext block has a common factor with n
```

```
plaintext_block = 59 # This is p (i.e., gcd(59, 3599) = 59)
```

```
p, q = gcd_attack(n, plaintext_block)
```

```
if p and q:
```

```
    print(f"Success! Factors of n found: p = {p}, q = {q}")
```

```
    phi = (p - 1) * (q - 1)
```

```
# Compute the private key using Extended Euclidean Algorithm
```

```
def mod_inverse(e, phi):
```

```
    def extended_gcd(a, b):
```

```
        if a == 0:
```

```
            return b, 0, 1
```

```
        gcd, x1, y1 = extended_gcd(b % a, a)
```

```
        x = y1 - (b // a) * x1
```

```
        y = x1
```

```
        return gcd, x, y
```

```
    gcd, x, _ = extended_gcd(e, phi)
```

```
    if gcd != 1:
```

```
        raise Exception("No modular inverse exists")
```

```
    return x % phi
```

```
d = mod_inverse(e, phi)
```

```
print(f"Private key d = {d}")
```

```
else:
```

```
    print("No common factor found; attack failed.")
```

OUTPUT:-

```
Success! Factors of n found: p = 59, q = 61
```

```
Private key d = 3031
```
